Israel: See Deeper.

Newly available broadband reprocessed 2D seismic in the Levant Basin, offshore Israel, dramatically improves our imaging of the biogenic plays and strengthens our understanding of the deeper geology and associated Mesozoic thermogenic hydrocarbon plays.

Enhancements in data quality greatly improve the intra and sub-salt imaging. In addition, deeper imagery now reveals previously unseen rift infill and dramatically increases confidence in the interpretation of the lower syn-rift and basement surfaces. This allows for better control on basin temperature models, seismic facies identification and analyses, as well as improved definition of potential traps. Improve your data. Improve your assessment. Improve your bid.

It’s time to see deeper in Israel.
